This sequence represents Erwinia herbicola phytoene dehydrogenase4H encoded by DNA from the plasmid pARC376. Phytoene dehydrogenase-4H has a encoded by DNA from the plasmid pARC376. Phytoene dehydrogenase-4H has a molified by DNA from the structural gene, presuming an average amino acid residue of about 100 bp for the structural gene, presuming an average amino acid residue of about 109. The native phytoene dehydrogenase-4H gene is located between positions 749 and 6380 of plasmid pARC376. Phytoene checknose and phytosenese of the phytosenese of the phytosenese of the prosphosphate. In E. herbicola, phytoene has been found to be formed prosphosphate. In E. herbicola, phytoene has been found to be formed prosphosphate in a two-step process. The initial step is the condensation of farnesyl pyrophosphate (FPP) and isopentyl pyrophosphate (FPP) and isopentyl pyrophosphate (FPP) and isopentyl pyrophosphate is produced from phytoene synthese, to form phytoene is produced from phytoene by the catalysed by the enzyme phytoene by the catalysed by the longent in the catalysed by the sensome phytoene by the catalysic action of phytoene is produced from phytoene by the catalysic action of phytoene is produced from phytoene by the catalysic action of phytoene commercial production of lycopene which is used as a food colourant.

Thanks transformed with the phytoene dehydrogenase-4H coding sequence are protected from the herbicide norfluxazon. (Updated on 25-MAR-2003 to standardise OS field)
                                                                                                                            E. herbicola, geranylgeranyl pyrophosphate synthase; pARC376; GGPP synthase; blosynthesis; carotenoid; lycopene; farnesyl pyrophosphate; phytoene; FPP; isopentyl pyrophosphate; IPP; tail to tail dimerisation; phytoene synthase; phytoene dehydrogenase-4H; food colourant; herbicide; norflurazon.
                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    encoding Erwinia herbicola phytoene dehydrogenase-4H - used for

```
A novel DNA molecule has been isolated which encodes an Erwinia herbicola lycopene cyclase enzyme that converts lycopene to beta-carotene. The DNA molecule comprises at 1825 bp and is present in the plasmids pARC1510, pARC1510. The present in the plasmids the amino acid sequence corresponding to the structural gene for phytosne dehygrogenase-4H. The new DNA molecule can be used to produce the recombinant enzyme and transgenic organisms, e.g. yeasts or plants, with increased beta-carotene levels. Beta-carotene is used as a colourant in margarine and butter and as an intermediate for vitamin A, and may prevent cancer. (Updated on 25-MAR-2003 to correct PF field.) (Updated on 17-OCT-2003 to standardise OS field)
                                                                                                   DNA encoding Erwinia herbicola lycopene cyclase - for producing recombinant enzyme, and transgenic organisms with increased beta-carotene

```
coli cells to produce GGPP and the carotemoids phytoene through seaxanthin diglucoside, which is the final prod. identified in the carotemoid pathway contd. in plasmid pARG376 (contg. a ca. 13 Kb chromosomal DNA fragment isolated by Perry et al., J. Bacteriol., i68:607 (1986). The genes for geranylgaranyl pyrophosphate (GGPP) synthase, phytoene synthase, phytoene dehydrogenase-4H, lycopene cyclase, beta-caroteme hydroxylase, and zeaxanthin glycosylase are represented in AAQ1316, AAQ1318, AAQ13712, AAQ13724 and AAQ13726 respectively. Recombinant expression plasmids can be used to produce large ants. of the enzymes and hence large ants. of the carotemoids which they synthesise. Carotemoids are pigments with a variety of applications (Updated on 25-MAR-2003 to correct PP field.) (Updated on 25-MAR-2003 to correct PP field.) (Updated on 25-MAR-2003 to correct PP field.)
                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        SAIBELFALAGKQLKDYVELLEVTPFYRLCWESGKVFNYDNDQAQLEAQIQQFNPRDVAG 120

                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       There are a total of six relevant genes in a 7900 bp region that cause B. coli cells to produce GGPP and the carotenoids phytoene through caexaranthin diglucoside, which is the final prod. identified in the carotenoid pathway contd. in plasmid pRAG376 (contg. a ca. 13 kb chromosomal DNA fragment isolated by Perry et al., J. Bacteriol., 168:607 [1986]. The genes for geranylgeranyl pyrophosphate (GGPP) synthase, phytoene synthase, phytoene dehydrogenase-44, lycopene cyclase, beta-carotene hydroxylase, and zeaxanthin glycosylase are represented in AAQ13712, AAQ13712, AAQ13722, AAQ13724 and AAQ13725 beta-respectively. Recombinant expression plasmids can be used to produce large amts. of the enzymes and hence large amts. of the carotenoids which they synthesise. Carotenoids are pigments with a variety of applications (Updated on 25-WAR-2003 to correct PP field.) (Updated on 25-WAR-2003 to correct PP field.)

```

Proffitt J, Mukharji I, Yarger J; Brinkhaus FL,

N-PSDB; AAT40793

Increasing prodn. of total carotenoid(s) in a higher plant - by transforming with vector encoding chloroplast transit peptide operably linked to the Erwinia herbicola lycopene cyclase structural gene.

Example 12; Col 97-100; 99pp; English

The present sequence is that of a recombinant Brwinia herbicola phytoene dehydrogenase-4H (from pARC146D) which produces lycopene biosynthetically from phytoene through four sequential dehydrogenation reactions. Other enzymes involved in the carotemoid biosynthesis pathway include geranylgeranyl pyrophosphate (AAM01119), phytoene synthase (Wol121) and lycopene cyclase (AAM01125). Manipulation of, in partic., lycopene cyclase (PAM01125), Manipulation of, in partic., lycopene cyclase gene (AAM01125), by in frame linkage to the chloroplast transit peptide (AAM01124) of the tobacco ribulose bis-phosphate carboxylase-oxygenase gene can lead to increased production of total carotemoids in the chloroplast of transformed plants as compared to native, nontransformed plants of the same type. Beta-carotene is an effective and apparently harmless food colourant and is also in the pathway for biological synthesis of further C40 carotemoids such as zeaxanthin and zeaxanthin diglucoside. (Updated on 25-MAR-2003 to correct PF field.)

Ronen G., Cohen M., Zamir D., Hirshberg J.;
Regulation of expression of the gene for lycopene epsilon cyclase during fruit ripening of tomato.";
Submitteed (Mar.1988) to the EMBL/Genenk/DDBJ databases.
-!- PUNCTION: CATALYZES THE SINGLE CYCLIZATION REACTION WHICH CONVERT INCOPENE TO DELTA-CAROTENE AND NEUROSPORENE TO ALPHA-ZEACAROTENE.
-!- SATHMAY CARCHAION: Chloroplast.
-!- SUBCELLULAR LOCATION: Chloroplast.
-!- SIMILARITY: Belongs to the lycopene cyclase family.
                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  16-OCT-2001 (Rel. 40, Created)

-:- FUNCTION: Catalyzes the double cyclization reaction which converts lycopene to beta-carotene and neurosporene to beta-zeacarotene.

-:- ENZYME REGULATION: INHIBITED BY THE BLEACHING HERBICIDE 2-(4-METHYLPHENOXY) TRIBITED BY THE BLEACHING HERBICIDE 2-(4-METHYLPHENOXY) TRIBITED BY THE PURPOSEDE (MPTA).

                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             -i- FUNCTION: Carealyzes the double cyclization reaction which converts lycopene to beta-carotene and neurosporene to beta-zeacarotene.
-i- PATHYMAY: Carotenoid biosynthesis.
-i- SUBCELLULAR LOCATION: Chloroplast; chromoplast. Exists as an inactive soluble form and an active membrane-bound form
                                                                                                                                                                             Bukaryota; Viridiplantae; Streptophyta; Embryophyta; Tracheophyta;

                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            District Cell 8:1613-1626(1996).
Plant Cell 8:1613-1626(1996).
-!- FUNCTION: Catalyzes the double cyclization reaction which converts lycopene to beta-carotene and neurosporene to beta-zeacarotene.
-!- PATHWAY: Carotenoid biosynthesis.
-!- SUBCELLUIAR LOCATION: Chloroplast.
                                                                                                                                                                                                                                                                                                                Spermatophyta; Viridiplantae; Streptophyta; Embryophyta; Tracheophyta; Spermatophyta; Magnoliophyta; eudicotyledons; core eudicots; asterids; lamiids; Solanales; Solanaceae; Nicotiana.

-i- PATHWAY: Carotenoid biosynthesis.
-i- SUBCELIULAR LOCATION: Chloroplast.
-i- SIMILARITY: Belongs to the lycopene cyclase family.
                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      STRAIN=cv.
